

**VICH GL27 (ANTIMICROBIAL RESISTANCE: PRE-APPROVAL)**

**December 2003**

**For implementation at Step 7 - Final**

# **GUIDANCE ON PRE-APPROVAL INFORMATION FOR REGISTRATION OF NEW VETERINARY MEDICINAL PRODUCTS FOR FOOD PRODUCING ANIMALS WITH RESPECT TO ANTIMICROBIAL RESISTANCE**

---

Recommended for Implementation  
at Step 7 of the VICH Process  
on 15 December 2004  
by the VICH Steering Committee

THIS GUIDELINE HAS BEEN DEVELOPED BY THE APPROPRIATE VICH EXPERT WORKING GROUP AND IS SUBJECT TO CONSULTATION BY THE PARTIES, IN ACCORDANCE WITH THE VICH PROCESS. AT STEP 7 OF THE PROCESS THE FINAL DRAFT WILL BE RECOMMENDED FOR ADOPTION TO THE REGULATORY BODIES OF THE EUROPEAN UNION, JAPAN AND USA.

# **Pre-Approval Information for Registration of New Veterinary Medicinal Products for Food-producing Animals with Respect to Antimicrobial Resistance**

## **Introduction**

The use of antimicrobial agents is likely to lead to selection of resistance whether administered to humans, animals or plants. Zoonotic organisms such as non-typhoid Salmonellae, *Campylobacter spp.* and enterohaemorrhagic *E. coli* (e.g. O157) can, by definition, be transferred to humans from animals. Therefore, it stands to reason that resistant zoonotic organisms can also be transferred to humans. The transfer of antimicrobial-resistant non-zoonotic bacteria or their genetic material from animals to humans via the food chain is also possible. However, data demonstrating the magnitude and importance of such transfer and whether such transfer occurs via consumption of contaminated meat or via contamination of water or vegetables by animal excreta are limited.<sup>1,2,3</sup> Humans are also a potential reservoir of antimicrobial-resistant microorganisms,<sup>4,5</sup>

The extent to which food-producing animals contribute to human exposure to antimicrobial-resistant microorganisms is difficult to quantify. However, when evaluating the safety of antimicrobial products for use in food-producing animals, regulatory authorities should consider the potential for such products to select for resistant bacteria. Therefore, guidance is needed for drug sponsors on the type of information that should be provided to the regulatory authorities. This information should help to characterize the potential for the use of the product to select for antimicrobial-resistant bacteria of human health concern. The information provided should be used as part of an overall assessment of the potential impact of the product on human health.

## **Objectives**

The objective of this document is to provide harmonized technical guidance in the E.U., Japan and the U.S. for registration of antimicrobial veterinary medicinal products intended for use in food-producing animals with regard to characterization of the potential for a given antimicrobial agent to select for resistant bacteria of human health concern.

For clarification, this guidance outlines the types of studies and data, which are recommended to characterize the potential resistance development as it might occur in the food-producing animal under the proposed conditions of use of the product. This includes information, which describes

attributes of the drug substance, the drug product, the nature of the resistance and the potential exposure of the gut flora in the target animal species. It does not account for post-slaughter factors such as processing of food products or kitchen hygiene that affect the potential human health impact.

Pathogen load studies, ecotoxicity studies, the process of risk assessment, the establishment of Acceptable Daily Intakes (ADIs), and consideration of residues of antimicrobial agents are not included in this guidance.

Special considerations may be appropriate for aquaculture products, because of fundamental differences in production systems, bacterial populations present, and potential zoonotic public health threats.

## **Data recommendations**

Information in the subsequent sections has been designated as 'basic' or 'additional' data. Where information is designated as 'basic', it is recommended that sponsors provide such information.

Where information is designated as 'additional', sponsors may choose to include some or all of those data. The proposed use conditions of the product, the potential exposure of animal gut flora to the antimicrobial agent, the potential exposure of humans to resistant bacteria or their resistance genes, and the perceived importance of the drug (or related drugs) to human medicine may be factors on which the sponsor provides 'additional' data.

## **1. Basic information**

### **1.1 Antimicrobial class**

This information can be based on the drug substance's chemical structure, patent information, and information that is contained in subsequent sections. For example, the common name, chemical name, CAS (Chemical Abstract Services) registry number, chemical structure, and manufacturer's code number and/or synonyms are recommended.

### **1.2 Mechanism and type of antimicrobial action**

This information may be inferred from literature studies, patent information, or specific mechanism of action studies undertaken by the sponsor. Characterization as to bacteriostatic vs. bactericidal action should be included in this section.

## 1.3 Antimicrobial spectrum of activity

### 1.3.1 General data

Information on the antimicrobial agent should be provided by the sponsor including data from MIC (minimum inhibitory concentration) tests against a wide variety of microorganisms or from literature studies, in order to determine the overall spectrum of activity. Where MICs are determined by the sponsor, the source of the isolates may be from culture collections, diagnostic laboratories, or other repositories.

Where possible, MIC values should be determined with a validated and controlled method, such as those described in National Committee on Clinical Laboratory Standards (NCCLS) documents (e.g., M31-A2, Performance Standards for Antimicrobial Disk and Dilution Susceptibility Tests for Bacteria Isolated from Animals; Approved Standard).

### 1.3.2 MICs of target animal pathogens (as per product label claim)

These data are considered supportive for the purposes of this guidance. Information on target animal pathogen MICs may be obtained from data within the Efficacy section of the dossier.

### 1.3.3 MICs of food-borne pathogens and commensal organisms

Data should be presented to show MICs of food-borne pathogens and commensal organisms.

This information may be based on published data or on studies done by the sponsor. Depending on the spectrum of activity, appropriate organisms may include:

Food-borne pathogens:

- *Salmonella enterica*
- *Campylobacter* spp.

Food-borne commensal organisms such as:

- *Escherichia coli*
- *Enterococcus* spp.

When possible, the strains included should be selected according to the following recommendations:

- Strains of relevant bacterial species/serotypes should be isolated from the proposed target animal species. When the product is intended for a broad range of animal species, the strains should be from the main food-producing species (e.g. cattle, pigs, and poultry).
- Preferably, the strain collection should include recent isolates.

Information on the tested strains should include:

- Identification at least to the species level.
- Origin, source and date of isolation.

#### **1.4 Antimicrobial resistance mechanisms and genetics**

Where possible, information on the resistance mechanism(s) and information on the molecular genetic basis of resistance to the antimicrobial agent should be provided. This information may come from literature or from studies done by the sponsor. Information from analogues may be provided in the absence of data on the drug substance.

#### **1.5 Occurrence and rate of transfer of antimicrobial resistance genes**

Information on the occurrence, or absence, of transfer and rate of transfer of resistance genes should be provided. This information may come from literature or from studies done by the sponsor. Specific studies to evaluate the occurrence of genetic transfer may follow a protocol such as found in *Antibiotics in Laboratory Medicine*, 4th ed., V. Lorian, ed. 1996. Williams and Wilkins, Baltimore, Maryland.

The sponsor may consider including data on target animal pathogens, relevant food-borne pathogens, and relevant commensal organisms. Information from analogues may be provided in the absence of data on the antimicrobial agent.

#### **1.6 Occurrence of cross-resistance**

Information on cross-resistance to the antimicrobial agent should be provided. This information may come from literature or studies done by the sponsor. This should include a phenotypic description and, if available, a genotypic description.

#### **1.7 Occurrence of co-resistance**

Information on co-resistance of the antimicrobial agent in question with other antimicrobial agents should be provided by literature information or studies done by the sponsor. This should include a phenotypic description and, if available, a genotypic description.

#### **1.8 Pharmacokinetic data**

Pharmacokinetic data may be obtained from other sections of the dossier in order to predict the antimicrobial activity in the intestinal tract. Data may include the following:

- Serum / plasma concentrations versus time data
- Maximum concentration (C<sub>max</sub>)
- Time of maximum concentration (T<sub>max</sub>)
- Volume of distribution (VD)

- Clearance (Cl)
- Area under the concentration-time curve (AUC)
- Bioavailability
- Protein binding

## **2. Additional information**

Sponsors may also choose to include some or all of the following:

### **2.1 *In vitro* mutation frequency studies**

*In vitro* mutation frequency studies involving test organisms may follow a protocol such as found in Antibiotics in Laboratory Medicine, 4th ed., V. Lorian, ed. 1996. Williams and Wilkins, Baltimore, Maryland.

### **2.2 Antimicrobial agent activity in intestinal tract**

Where available, details may be provided on the concentrations of microbiologically-active compound within the intestinal tract contents or the faeces when the antimicrobial product is administered according to the proposed conditions of use. The activity in question may be due to the parent antimicrobial agent, or to active metabolites.

Where such data are not available, details may be provided by metabolism studies relevant to the intestinal tract. Data from metabolism studies may be obtained from other sections of the dossier.

### **2.3 Other animal studies**

The sponsor may choose to include information from other animal studies conducted to help characterize the rate and extent of resistance development associated with the proposed use of the antimicrobial product. This may include data from clinical studies conducted in support of other sections of the dossier.

The predictive value of the results of such studies is yet to be established with regards to resistance development. Therefore the results of such studies should be interpreted in the context of all other pre-approval information described in this document.

### **2.4 Supporting information**

When available and relevant, supporting information from literature or studies on previously approved uses of the drug product or related products may be provided.

## **3. Discussion**

The sponsor should characterize the potential for the use of the product to select for antimicrobial-resistant bacteria of human health concern. To accomplish this, the sponsor should

discuss the information provided in the previous sections in terms of the exposure of food-borne pathogens and commensal organisms to microbiologically active substance in the target animal after administration of the veterinary medicinal product under the proposed conditions of use.

## **Glossary**

Antimicrobial agent or antimicrobial(s): naturally occurring, semi-synthetic or synthetic substances that exhibit antimicrobial activity (kill or inhibit the growth of other micro-organisms).

Food-producing animals: Cattle, poultry and pigs are considered as food-producing animals. Because of regional differences, in some countries other animal species may be considered as food-producing animals.

Target animal pathogen: pathogenic bacterial species causing infection in the target animals for which the veterinary antimicrobial medicinal product is indicated to be used for, as claimed on the label.

Food-borne pathogens: zoonotic organisms, of which animals could be carriers in the intestinal content, that could be transmitted to humans by the food chain and subsequently cause food-borne infections in humans.

Food-borne commensal organisms: non-zoonotic bacterial species, living in the intestinal content of animals, that could be transmitted to humans by the food chain and that normally do not cause food-borne infections in humans.
